(57) **ABSTRACT**

A light emitting diode includes a first semiconductor layer, an active layer, a second semiconductor layer, and a cermet layer. The active layer is on the first semiconductor layer. The second semiconductor layer is on the active layer. The cermet layer is on the second semiconductor layer. A first electrode covers entire surface of the first semiconductor layer away from the active layer. A second electrode is electrically connected to the second semiconductor layer.

LIGHT EMITTING DIODE**CROSS-REFERENCE TO RELATED APPLICATIONS**

This application claims all benefits accruing under 35 U.S.C. §119 from China Patent Application No. 201210185706.0, filed on Jun. 7, 2012, in the China Intellectual Property Office, the contents of which are hereby incorporated by reference. This application is related to commonly-assigned applications entitled, "SEMICONDUCTOR STRUCTURE", filed on Dec. 28, 2012, with application Ser. No. 13/729,588; "METHOD FOR MAKING LIGHT EMITTING DIODE", filed on Dec. 28, 2012, with application Ser. No. 13/729,627, the contents of the above commonly-assigned applications are hereby incorporated by reference.

BACKGROUND**1. Technical Field**

The present disclosure relates to semiconductor structures, a light emitting diode, and a method for making the same.

2. Description of Related Art

Semiconductor structures fabricated by gallium nitride for light sources, such as blue, green, and white light sources, have long lifetime, high energy conversion efficiency, and are green. Therefore, the semiconductor structures are widely used as the light sources in large screen color display systems, automotive lighting, traffic lights, multimedia displays, optical communication systems, and so on.

A semiconductor structure used in a standard light emitting diode (LED) includes an N-type semiconductor layer, a P-type semiconductor layer, and an active layer located between the N-type semiconductor layer and the P-type semiconductor layer. In operation, a positive voltage and a negative voltage are applied respectively to the P-type semiconductor layer and the N-type semiconductor layer. Thus, holes in the P-type semiconductor layer and electrons in the N-type semiconductor layer can enter the active layer and combine with each other to emit visible light, and the visible light is emitted from the semiconductor structure. However, near field evanescent waves emitted from the active layer are internally reflected inside the semiconductor structure, so that a large portion of the light emitted from the active layer remain in the semiconductor structure, thereby degrading the light extraction efficiency of the LED.

What is needed, therefore, is to provide a semiconductor structure for solving the problem discussed above.

BRIEF DESCRIPTION OF THE DRAWING

Many aspects of the present disclosure can be better understood with reference to the following drawings. The components in the drawings are not necessarily to scale, the emphasis instead being placed upon clearly illustrating the principles of the present embodiments. Moreover, in the drawings, like reference numerals designate corresponding parts throughout the several views.

FIG. 1 is a schematic sectional view of one embodiment of a semiconductor structure.

FIG. 2 is a schematic sectional view of one embodiment of a semiconductor structure.

FIG. 3 is a schematic sectional view of one embodiment of a semiconductor structure.

FIG. 4 is a schematic sectional view of one embodiment of a semiconductor structure.

2

FIG. 5 is a schematic sectional view of one embodiment of a three dimensional structure array of FIG. 4.

FIG. 6 is a scanning electron microscope image of FIG. 5.

FIG. 7 is a schematic view of one embodiment of an LED.

FIG. 8 is a flowchart of one embodiment of a method for making the LED of FIG. 7.

FIG. 9 is a schematic view of one embodiment of an LED.

FIG. 10 is a flowchart of one embodiment of a method for making the LED of FIG. 9.

FIG. 11 is a schematic view of one embodiment of an LED.

FIG. 12 is a schematic view of one embodiment of an LED.

FIG. 13 is a schematic view of one embodiment of a solar cell.

FIG. 14 is a schematic view of one embodiment of a wave guide tube.

FIG. 15 is a figure that shows a relationship between the Angular frequency and the Purcell Factor of the LED of FIG. 7.

DETAILED DESCRIPTION

The disclosure is illustrated by way of example and not by way of limitation in the figures of the accompanying drawings in which like references indicate similar elements. It should be noted that references to "another," "an," or "one" embodiment in this disclosure are not necessarily to the same embodiment, and such references mean at least one.

Referring to FIG. 1, one embodiment of a semiconductor structure 10 includes a substrate 110 having an epitaxial growth surface 112, a buffer layer 116, a first semiconductor layer 120, an active layer 130, a second semiconductor layer 140, a protective layer 150, and a cermet layer 160. The buffer layer 116, the first semiconductor layer 120, the active layer 130, the second semiconductor layer 140, the protective layer 150, and the cermet layer 160 are stacked on the epitaxial growth surface 112 in that sequence.

The substrate 110 can be a transparent structure having an epitaxial growth surface 112 used to grow the first semiconductor layer 120. The epitaxial growth surface 112 is a smooth surface. Oxygen and carbon are removed from the epitaxial growth surface 112. The substrate 110 can be a single layer structure or a multiple layer structure. If the substrate 110 is a single layer structure, the substrate 110 can be a single-crystal structure. The single-crystal structure includes a crystal face which is used as the epitaxial growth surface 112. A material of the substrate 110 can be silicon on insulator (SOI), LiGaO₂, LiAlO₂, Al₂O₃, Si, GaAs, GaN, GaSb, InN, InP, InAs, InSb, AlP, AlAs, AlSb, AlN, GaP, SiC, SiGe, GaMnAs, GaAlAs, GaInAs, GaAlN, GaInN, AlInN, GaAsP, InGaN, AlGaInN, AlGaInP, GaP:Zn, or GaP:N. If the substrate 110 is the multiple layer structure, the substrate 110 should include at least one layer of the single-crystal structure mentioned previously. The material of the substrate 110 can be selected according to the first semiconductor layer 120. In one embodiment, a lattice constant and thermal expansion coefficient of the substrate 110 is similar to the first semiconductor layer 120 thereof to improve a quality of the first semiconductor layer 120. In one embodiment, the material of the substrate 110 is sapphire. A thickness, shape, and size of the substrate 110 are arbitrary and can be selected according to need.

The buffer layer 116 is sandwiched between the substrate 110 and the first semiconductor layer 120. A thickness of the buffer layer 116 ranges from about 10 nanometers to about 300 nanometers, such as about 20 nanometers and about 50 nanometers. A material of the buffer layer 116 can be GaN, or AlN with low melting point. In one embodiment, the material

of the buffer layer **116** is GaN, and the thickness of the buffer layer **116** is about 20 nanometers.

A thickness of the first semiconductor layer **120** can be in a range from about 1 micrometer to about 15 micrometers. The first semiconductor layer **120** can be a doped semiconductor layer. The doped semiconductor layer can be an N-type semiconductor layer or a P-type semiconductor layer. A material of the N-type semiconductor layer can be at least one of N-type GaN, N-type GaAs, and N-type cupric phosphide. A material of the P-type semiconductor layer can be at least one of P-type GaN, P-type GaAs, and P-type cupric phosphide. The N-type semiconductor layer is configured to provide electrons, and the P-type semiconductor layer is configured to provide holes. In one embodiment, the material of the first semiconductor layer **120** is the N-type GaN doped with Si element, and the thickness of the first semiconductor layer **120** is about 1460 nanometers.

The active layer **130** is a photon excitation layer to provide a location for the combination of the electrons and holes. Photons are produced in the active layer **130** when the electrons and holes are combined. The active layer **130** can be one of a single layer quantum well film or multilayer quantum well film. A material of the quantum well film can be at least one of GaInN, AlGaInN, GaAs, GaAlAs, GaInP, InAsP, and InGaAs. A thickness of the active layer **130** can be in a range from about 0.01 micrometers to about 0.6 micrometers. In one embodiment, the material of the active layer **130** is a composition of InGaIn and GaN, and the thickness of the active layer **130** is about 10 nanometers.

The second semiconductor layer **140** can be the N-type semiconductor layer or the P-type semiconductor layer. The type of the first semiconductor layer **120** and the type of the second semiconductor layer **140** is different to form a PN junction. The second semiconductor layer **140** is located on the active layer **130**. A thickness of the second semiconductor layer **140** ranges from about 5 nanometers to about 250 nanometers. In one embodiment, the thickness of the second semiconductor layer **140** ranges from about 10 nanometers to about 200 nanometers. In one embodiment, the thickness of the second semiconductor layer **140** is in a range from about 10 nanometers to about 30 nanometers. The thickness of the second semiconductor layer **140** can be about 10 nanometers, about 50 nanometers, about 100 nanometers, or about 200 nanometers. In one embodiment, the second semiconductor layer **140** is the P-type GaN doped with Mg element, and the thickness of the second semiconductor layer **140** is about 10 nanometers. In one embodiment, the refractive index of the composite semiconductor layer **200** is about 2.5.

The protective layer **150** is located on the second semiconductor layer **140**. The protective layer **150** is sandwiched between the second semiconductor layer **140** and the cermet layer **160**. The protective layer **150** can prevent the metallic plasma generated by the cermet layer **160** from converting to heat. The refractive index of the cermet layer **160** under a guided wave mode is a complex number including a real part and an imaginary part. If the imaginary part is large, the metallic plasma is easily converted to heat. Thus, the protective layer **150** is made of a material with a low refractive index and can reduce the real part and the imaginary part at the same time. Thus, the heat consumption of the metallic plasma can be reduced, and the metallic plasma can travel farther. Therefore, the extraction efficiency of the semiconductor structure **10** can be increased. In one embodiment, the refractive index of the protective layer **150** can be in a range from about 1.2 to about 1.5. In one embodiment, the refractive index of the protective layer **150** is in a range from about 1.3 to about 1.4. In one embodiment, the refractive index of the protective

layer **150** is in a range from about 1.4 to about 1.5. The material of the protective layer **150** can be silicon dioxide, magnesium fluoride, or lithium fluoride. In one embodiment, the material of the protective layer **150** is silicon dioxide, and the refractive index of the protective layer **150** is about 1.5.

A thickness of the protective layer **150** can be in a range from about 5 nanometers to about 40 nanometers. In one embodiment, the thickness of the protective layer **150** is in a range from about 5 nanometers to about 10 nanometers. In one embodiment, the thickness of the protective layer **150** is in a range from about 10 nanometers to about 20 nanometers. In one embodiment, the thickness of the protective layer **150** is in a range from about 20 nanometers to about 30 nanometers. In one embodiment, the thickness of the protective layer **150** is in a range from about 30 nanometers to about 40 nanometers. The thinner the protective layer **150**, the closer the cermet layer **160** and active layer **130**. Therefore, the interaction between the cermet layer **160** and the active layer **130** will be improved, and more photos will be generated by the active layer **130**. In one embodiment, the thickness of the protective layer **150** is about 20 nanometers.

A material of the cermet layer **160** can be selected to ensure that the cermet layer **160** can generate metallic plasma. Therefore, the material of the cermet layer **160** is metallic in optics. Furthermore, the material of the cermet layer **160** can satisfy the following requirements. First, the refractive index of the cermet layer **160** is a complex number including a real part and an imaginary part, and the imaginary part cannot be zero. Second, a dielectric constant of the cermet layer **160** is a complex number including a real part and an imaginary part, and the real part is a negative number.

The material of the cermet layer **160** can be a metallic composite, and the metallic composite can include a metal material and a dielectric material, such as metal ceramic. Thus lights with long wavelengths can be easily extracted from the active layer **130**. The metal can be silver, aluminum, copper or gold. The alloy can be gold-silver alloy, gold-aluminum alloy, or silver-aluminum alloy. The dielectric material can be silicon, silicon dioxide, or ceramic. A mass percent of the dielectric material in the metallic composite can be less than or equal to 40%, such as about 35%, about 30%, about 25%, about 20%, about 15%, about 10%, or about 5%. In one embodiment, the metal in the cermet layer **160** is silver, and the dielectric material is silicon dioxide. A thickness of the cermet layer **160** can be in a range from about 50 nanometers to about 100 nanometers. The thickness of the cermet layer **160** can be selected to ensure that the photons generated by the active layer **130** can be extracted out through the substrate **110**. In one embodiment, the thickness of the cermet layer **160** is about 50 nanometers.

Furthermore, the substrate **110** is optional and can also be omitted from the semiconductor structure **10**.

The cermet layer **160** has many functions. Near field evanescent waves generated by the active layer **130** can be amplified and converted to metallic plasma by the cermet layer **160**, when arriving at the cermet layer **160**. The metallic plasma can be extracted out of the semiconductor structure **10** through the substrate **110**. A few metallic plasma can be scattered by the cermet layer **160** and spread around the cermet layer **160**. While the metallic plasma reaches the active layer **130**, the metallic plasma can interact with the quantum well in the active layer **130** to activate more secondary photons. The secondary photons can also arrive at the cermet layer **160** and introduce more metallic plasma. Thus, more photons can be extracted out of the semiconductor structure **10** under the interaction between the cermet layer

160 and the active layer 130. Furthermore, the uniformity of the current distributed in the second semiconductor layer 140 can be improved.

Also referring to FIG. 2, one embodiment of a semiconductor structure 20 is provided. The semiconductor structure 20 includes a substrate 110 having an epitaxial growth surface 112, a buffer layer 116, a first semiconductor layer 120, an active layer 130, a second semiconductor layer 140, and a cermet layer 160. The buffer layer 116, the first semiconductor layer 120, the active layer 130, the second semiconductor layer 140, and the cermet layer 160 are stacked on the epitaxial growth surface 112 in that sequence.

The semiconductor structure 20 is similar to the semiconductor structure 10, except that the protective layer 150 is omitted. The cermet layer 160 is directly located on a surface of the second semiconductor layer 140. Thus a distance between the cermet layer 160 and the active layer 130 is reduced, and the interaction between them is improved.

Referring to FIG. 3, one embodiment of a semiconductor structure 30 includes a substrate 110 having an epitaxial growth surface 112, a first semiconductor layer 120, an active layer 130, a second semiconductor layer 140, a protective layer 150, and a cermet layer 160. The first semiconductor layer 120, the active layer 130, the second semiconductor layer 140, the protective layer 150, and the cermet layer 160 are stacked on the epitaxial growth surface 112 in that sequence.

The semiconductor structure 30 is similar to the semiconductor structure 10, except that the buffer layer 116 is omitted. The first semiconductor layer 120 is directly located on the epitaxial growth surface 112 of the substrate 110.

Referring to FIG. 4, one embodiment of a semiconductor structure 40 is provided. The semiconductor structure 40 includes a first semiconductor layer 120, an active layer 130, a second semiconductor layer 140, a protective layer 150, and a cermet layer 160 stacked in that order. The semiconductor structure 40 is similar to the semiconductor structure 20, except that a surface of the second semiconductor layer 140 away from the active layer 130 includes a plurality of primary three-dimensional nano-structures 143.

Also referring to FIG. 5, the second semiconductor layer 140 can be separated into a main body 140a and a protruding part 140b and distinguished by an "interface." The interface can be parallel with the first surface of the second semiconductor layer 140. The interface is configured as a surface of the main body 140a, and the protruding part 140b is extending away from the interface. The protruding part 140b defines the plurality of primary three-dimensional nano-structures 143, and the plurality of primary three-dimensional nano-structures 143 form the patterned surface of the second semiconductor layer 140. The three-dimensional nano-structure 143 can be a protruding structure. The protruding structure protrudes out from the interface of the main body 140a. The plurality of primary three-dimensional nano-structures 143 is a protruding structure located on the interface of the main body 140a.

The plurality of primary three-dimensional nano-structures 143 can be arranged side by side. Each of the primary three-dimensional nano-structures 143 can extend along a straight line, a curvy line, or a polygonal line. The extending direction is substantially parallel with the surface of the second semiconductor layer 140. The two adjacent three-dimensional nano-structures are arranged a certain distance apart from each other. The distance ranges from about 0 nanometers to about 1000 nanometers, such as about 10 nanometers, about 30 nanometers, or about 200 nanometers. The extending direction of the three-dimensional nano-structure 143 can

be fixed or varied. While the extending direction of the three-dimensional nano-structure 143 is fixed, the plurality of primary three-dimensional nano-structures 143 extends along a straight line. Otherwise the primary three-dimensional nano-structures 143 extends along a polygonal line or a curvy line. The cross-section of the three-dimensional nano-structure 143 along the extending direction is M-shaped. Referring to FIG. 5 and FIG. 6, the primary three-dimensional nano-structures 143 are a plurality of substantially parallel bar-shaped protruding structures extending along a straight line. The plurality of primary three-dimensional nano-structures 143 are substantially uniformly and equidistantly distributed on the entire surface of the main body 140a.

The three-dimensional nano-structure 143 extends from one side of the second semiconductor layer 140 to the opposite side along the X direction. The Y direction is substantially perpendicular to the X direction and substantially parallel with the surface of the main body 140a. The three-dimensional nano-structure 143 is a double-peak structure including two peaks. The cross-section of the double-peak structure is in the shape of an M. Each M-shaped three-dimensional nano-structure 143 includes a first peak 1132 and a second peak 1134. The first peak 1132 and the second peak 1134 extend substantially along the X direction. A first groove 1136 is defined between the first peak 1132 and the second peak 1134. A second groove 1138 is defined between two adjacent primary three-dimensional nano-structures 143.

The first peak 1132 and the second peak 1134 protrude out of the main body 140a. The height of the first peak 1132 and the second peak 1134 is arbitrary and can be selected according to need. In one embodiment, both the height of the first peak 1132 and that of the second peak 1134 range from about 150 nanometers to about 200 nanometers. The height of the first peak 1132 can be substantially equal to that of the second peak 1134. The highest points of the first peak 1132 and the second peak 1134 are defined as the farthest point away from the surface of the main body 140a. In one three-dimensional nano-structure 143, the highest point of the first peak 1132 is spaced from that of the second peak 1134 a certain distance ranging from about 20 nanometers to about 100 nanometers. The first peak 1132 and the second peak 1134 extend substantially along the X direction. The cross-section of the first peak 1132 and the second peak 1134 can be trapezoidal or triangular, and the shape of the first peak 1132 and the second peak 1134 can be substantially the same. In one embodiment, the cross-sections of the first peak 1132 and the second peak 1134 are triangular. In one embodiment, the first peak 1132, the second peak 1134, and the main body 140a form an integrated structure.

In each M-shaped three-dimensional nano-structure 143, the first peak 1132 and the second peak 1134 define the first groove 1136. The extending direction of the first groove 1136 is substantially the same as the extending direction of the first peak 1132 and the second peak 1134. The cross-section of the first groove 1136 is V-shaped. The depth h_1 of the first groove 1136 in each three-dimensional nano-structure 143 is substantially the same. The depth h_1 is defined as the distance between the highest point of the first peak 1132 and the lowest point of the first groove 1136. The depth of the first groove 1136 is less than the height of the first peak 1132 and the second peak 1134.

The second groove 1138 extends substantially along the extending direction of the primary three-dimensional nano-structures 143. The cross-section of the second groove 1138 is V-shaped or an inverse trapezium. Along the extending direction, the cross-section of the second groove 1138 is substantially the same. The depth h_2 of the second grooves 1138

between adjacent primary three-dimensional nano-structures **143** is substantially the same. The depth h_2 is defined as the distance between the highest point and the lowest point of the groove of the second groove **1138**. The depth of the second groove **1138** is greater than the depth of the first groove **1136**, and the ratio between h_1 and h_2 ranges from about 1:1.2 to about 1:3 ($1:1.2 \leq h_1:h_2 \leq 1:3$). The depth of the first groove **1136** ranges from about 30 nanometers to about 120 nanometers, and the depth of the second groove **1138** ranges from about 90 nanometers to about 200 nanometers. In one embodiment, the depth of the first groove **1136** is about 80 nanometers, and the depth of the second groove **1138** is about 180 nanometers. The depth of the first groove **1136** and the second groove **1138** can be selected according to need.

The protective layer **150** and the cermet layer **160** are stacked on the patterned surface of the second semiconductor conductive layer **140**. Furthermore, the surface of the protective layer **150**, and the surface of the cermet layer **160** away from the active layer **130** can also form a secondary patterned surface. The secondary patterned surface is similar to the patterned surface of the second semiconductor layer **140**. The secondary patterned surface also includes a plurality of secondary three-dimensional nano-structures **163**, and the distribution and the alignment of the secondary three-dimensional nano-structures **163** are the same as the distribution and the alignment of primary three-dimensional nano-structures **143**.

Furthermore, if the protective layer **150** is omitted, the cermet layer **160** is directly located on the surface of the second semiconductor layer **140**. The surface of the cermet layer **160** away from the cermet layer **160** can also form the plurality of secondary three-dimensional nano-structures **163**.

The semiconductor structure has many advantages. First, the plurality of primary three-dimensional nano-structures **143** change the motion direction of the photons reaching the light emitting surface with a large incident angle, so that these photons can be extracted from the light emitting surface. Second, the metallic plasma can be scattered by the plurality of well aligned three-dimensional nanostructures **143** on the cermet layer, thus the metallic plasma can be easily extracted. Third, because the three-dimensional nano-structure **143** is M-shaped, the M-shaped primary three-dimensional nano-structures **143** can function as two layers of the three-dimensional nano-structure assembled together. The light extraction efficiency of the semiconductor structure will be improved.

Furthermore, the surface of the first semiconductor layer **120** adjacent to the active layer **130** can also be a patterned surface including a plurality of three-dimensional nanostructures (now shown). Therefore, the contact area between the first semiconductor layer **120** and the active layer **130** can be enlarged. The electron-hole recombination density is improved, and the quantity of photons is increased. The light extraction efficiency of the semiconductor structure **30** can be improved.

Also referring to FIG. 7, one embodiment of an LED **50** includes a first semiconductor layer **120**, an active layer **130**, a second semiconductor layer **140**, and a cermet layer **160** stacked in that order. The first semiconductor layer **120** includes a first surface **121** and a second surface **122** opposite to the first surface. The active layer **130** is located on the second surface **122**. A first electrode **124** covers and directly contacts the first surface **121** of the first semiconductor layer **120** away from the active layer **130**. A second electrode **144** is electrically connected to the second semiconductor layer **140**. In one embodiment, a part of the surface of the second semi-

conductor layer **140** is exposed, and the second electrode **144** is located on the exposed surface of the second semiconductor layer **140**.

The first electrode **124** is electrically connected with the first semiconductor layer **120**. The first electrode **124** can cover the entire surface of the first semiconductor layer **120** away from the active layer **130**. Thus the LED **50** forms a vertical structure, and the current diffusion speed will be improved and the heat produced in the LED **50** will be decreased. The first electrode **124** is a single layer structure or a multi-layer structure. The first electrode **124** can be an N-type electrode or a P-type electrode according to the first semiconductor layer **120**. The material of the first electrode **124** can be selected from Ti, Ag, Al, Ni, Au, or any combination of them. The material of the first electrode **124** can also be indium-tin oxide (ITO) or carbon nanotube film. In one embodiment, the first electrode **124** is a two-layer structure consisting of a Ti layer with about 15 nm in thickness and an Au layer with about 100 nm in thickness.

The second electrode **144** can be an N-type electrode or a P-type electrode. The type of the second electrode **144** is the same as the second semiconductor layer **140**. The shape of the second electrode **144** is arbitrary and can be selected according to need. The second electrode **144** covers at least part of the surface of the second semiconductor layer **140**. The second electrode **130** can cover at least part of the three-dimensional nano-structures **142**. The shape and the location of the second electrode **144** cannot affect the light extraction efficiency of the LED **50**. The second electrode **144** is a single layer structure or a multi-layer structure. The material of the second electrode **144** can be selected from Ti, Ag, Al, Ni, Au or any combination of them. The material of the second electrode **144** can also be ITO. In one embodiment, the second electrode **144** is transparent to reduce the reflectivity and the absorption, thus improving the light extraction efficiency.

Also referring to FIG. 8, one embodiment of a method for making the LED **50** includes the following steps:

(S610), providing a substrate **110** having an epitaxial growth surface **112**;

(S620), growing a first semiconductor layer **120**, an active layer **130**, and a second semiconductor layer **140** on the epitaxial growth surface **112** in that order;

(S630), applying a cermet layer **160** on the second semiconductor layer **140**;

(S640), removing the substrate **110** to expose a surface of the first semiconductor layer **120**; and

(S650), applying a first electrode **124** to cover the exposed surface of the first semiconductor layer **120**, and a second electrode **144** electrically connected to the second semiconductor layer **140**.

In step (S620), the first semiconductor layer **120**, the active layer **130** and the second semiconductor layer **140** can be grown respectively via a process of molecular beam epitaxy (MBE), chemical beam epitaxy (CBE), vacuum epitaxy, low temperature epitaxy, choose epitaxy, liquid phase deposition epitaxy (LPE), metal organic vapor phase epitaxy (MOVPE), ultra-high vacuum chemical vapor deposition (UHVCVD), hydride vapor phase epitaxy (HYPE), and metal organic chemical vapor deposition (MOCVD).

In one embodiment, the first semiconductor layer **120** is Si-doped N-type GaN. The first semiconductor layer **120** is made by a MOCVD method, and the growth of the first semiconductor layer **120** is a heteroepitaxial growth. In the MOCVD method, the nitrogen source gas is high-purity ammonia (NH_3), the carrier gas is hydrogen (H_2), the Ga source gas is trimethyl gallium (TMGa) or triethyl gallium (TEGa), and the Si source gas is silane (SiH_4). The growth

method of the active layer **130** is similar to the first semiconductor layer **120**. In one embodiment, the indium source gas is trimethyl indium. The second semiconductor layer **140** is grown after the growth of the active layer **130**. In one embodiment, the Mg source gas is ferrocene magnesium (Cp_2Mg).

In step (S630), the cermet layer **160** can be deposited on the second semiconductor layer **140** by sputtering or vacuum evaporation. In one embodiment, the material of the cermet layer **160** includes silver and silicon dioxide. The cermet layer **160** can be deposited on the second semiconductor layer by the following method:

(S631), providing a melted silver and a melted silicon dioxide;

(S632), forming a melted alloy by mixing the melted silver and the melted silicon dioxide, wherein the mass percent of the melted silicon dioxide is about 20%; and

(S633), evaporating the melted alloy and depositing the melted alloy on the second semiconductor layer **140**.

In step (S640), the substrate **110** can be removed by laser irradiation, etching, or thermal expansion and contraction. The removal method can be selected according to the material of the substrate **110** and the first semiconductor layer **120**. In one embodiment, the substrate **110** is removed by laser irradiation. The substrate **110** can be removed from the first semiconductor layer **120** by the following steps:

(S641) polishing and cleaning the surface of the substrate **110** away from the first semiconductor layer **120**;

(S642) placing the substrate **110** on a platform (not shown) and irradiating the substrate **110** and the first semiconductor layer **120** with a laser; and

(S643) immersing the substrate **110** into a solvent and removing the substrate **110**.

In step (S641), the substrate **110** can be polished by a mechanical polishing method or a chemical polishing method to obtain a smooth surface. Thus the scattering of the laser will be decreased. The substrate **110** can be cleaned with hydrochloric acid or sulfuric acid to remove the metallic impurities and oil.

In step (S642), the substrate **110** is irradiated by the laser from the polished surface, and the incidence angle of the laser is substantially perpendicular to the surface of the substrate **110**. The wavelength of the laser is selected according to the material of the first semiconductor layer **120** and the substrate **110**. The energy of the laser is smaller than the bandgap energy of the substrate **110** and larger than the bandgap energy of the first semiconductor layer **120**. Thus the laser can pass through the substrate **110** and reach the interface between the substrate **110** and the first semiconductor layer **120**. The buffer layer at the interface has a strong absorption of the laser, and the temperature of the buffer layer will be raised rapidly. Thus the buffer layer will be decomposed. In one embodiment, the bandgap energy of the first semiconductor layer **120** is about 3.3 eV, and the bandgap energy of the substrate **110** is about 9.9 eV. The laser is a KrF laser, the wavelength of the laser is about 248 nm, the energy is about 5 eV, the pulse width range is about 20 nanoseconds to about 40 nanoseconds, the energy density ranges from about 400 mJ/cm² to about 600 mJ/cm², and the shape of the laser pattern is square with a size of about 0.5 mm×0.5 mm. The laser moves from one edge of the substrate **110** with a speed of about 0.5 mm/s. During the irradiating process, the GaN is decomposed to Ga and N₂. The parameter of the laser and the wavelength of the laser can be selected according to the absorption of the buffer layer.

Because the buffer layer has a strong absorption of the laser, the buffer layer can decompose rapidly. However, the first semiconductor layer **120** has a weak absorption, so it

does not decompose quickly. The irradiating process can be performed in a vacuum or a protective gas environment. The protective gas can be nitrogen, helium, argon, or other inert gas.

In step (S643), the substrate **110** can be immersed into an acidic solution to remove the Ga decomposed from GaN so that the substrate **110** can be peeled off from the first semiconductor layer **120**. The acidic solution can be hydrochloric acid, sulfuric acid, or nitric acid which can dissolve the Ga.

In step (S650), the first electrode **124** and the second electrode **144** can be formed via a process of physical vapor deposition, such as electron beam evaporation, vacuum evaporation, ion sputtering, or any physical deposition. Furthermore, a conductive substrate (not shown) can be directly attached on and electrically connected to the first semiconductor layer **120**, and the conductive substrate can be used as the first electrode **124**.

Also referring to FIG. 9, one embodiment of an LED **60** includes a first semiconductor layer **120**, an active layer **130**, a second semiconductor layer **140**, a protective layer **150**, and a cermet layer **160** stacked in that order. The first semiconductor layer **120** includes a first surface **121** and a second surface **122** opposite to the first surface. The active layer **130** is located on the second surface **122**. A first electrode **124** covers and directly contacts the first surface **121** of the first semiconductor layer **120** away from the active layer **130**. A second electrode **144** is electrically connected to the second semiconductor layer **140**. In one embodiment, a part surface of the second semiconductor layer **140** is exposed, and the second electrode **144** is located on the exposed surface of the second semiconductor layer **140**.

The structure of the LED **60** is similar to the structure of the LED **50**, except that the LED **60** further includes a protective layer **150** sandwiched between the second semiconductor layer **140** and the cermet layer **160**.

Also referring to FIG. 10, one embodiment of a method for making the LED **60** includes the following steps:

(S810), providing a substrate **110** having an epitaxial growth surface **112**;

(S820), growing a first semiconductor layer **120**, an active layer **130**, and a second semiconductor layer **140** on the epitaxial growth surface **112** in that order;

(S830), applying a protective layer **150** on the second semiconductor layer **140**;

(S840), applying a cermet layer **160** on the protective layer **150**;

(S850), removing the substrate **110** to expose a surface of the first semiconductor layer **120**; and

(S860), applying a first electrode **124** to cover the exposed surface of the first semiconductor layer **120**, and a second electrode **144** electrically connected to the second semiconductor layer **140**.

The method of making the LED **60** is similar to the method of making the LED **50**, except an additional step of locating the protective layer **150** on the second semiconductor layer **140**. The protective layer **150** can be deposited on the second semiconductor layer **140** via sputtering, chemical vapor deposition, or vacuum evaporation. In one embodiment, a material of the protective layer **150** is silicon dioxide, and the thickness of the protective layer **150** is about 130 nanometers. The protective layer **150** can be deposited on the second semiconductor layer **140** via chemical vapor deposition.

Also referring to FIG. 11, one embodiment of an LED **70** includes a first semiconductor layer **120**, an active layer **130**, a second semiconductor layer **140**, a protective layer **150**, and a cermet layer **160** stacked in that order. The first semiconductor layer **120** includes a first surface **121** and a second

surface **122** opposite to the first surface. The active layer **130** is located on the second surface **122**. A first electrode **124** covers and directly contacts the first surface **121** of the first semiconductor layer **120** away from the active layer **130**. A second electrode **144** is electrically connected to the second semiconductor layer **140**.

The structure of the LED **70** is similar to the structure of the LED **60**, except that the second semiconductor layer **140** further includes a plurality of primary three-dimensional nano-structures **143**. The plurality of primary three-dimensional nano-structures **143** is applied on the surface of the second semiconductor layer **140** away from the active layer **130**. The structure of the plurality of primary three-dimensional nano-structures **143** of LED **70** is similar to that in the semiconductor structure **30**. Thus the light extractive efficiency of LED **70** will be improved. Referring to FIG. **11**, the light extractive efficiency of LED **70** is much greater than that of the standard LED and the standard only with three-dimensional nano-structures.

Furthermore, the plurality of three-dimensional nano-structures can also be applied on a surface of the first semiconductor layer **120** adjacent to the active layer **130**, or a surface of the active layer **130** adjacent to the second semiconductor layer **140**. Therefore, the contact area between the first semiconductor layer **120** and the active layer **130**, or between the second semiconductor layer **140** and the active layer **130**, can be enlarged. The electron-hole recombination density is improved, and the quantity of photons is increased. The light extraction efficiency of the LED **70** can be improved.

The method of one embodiment of making the LED **70** includes:

(S710), providing a substrate **110** having an epitaxial growth surface **112**;

(S720), growing a first semiconductor layer **120**, an active layer **130**, and a second semiconductor layer **140** on the epitaxial growth surface **112** in that order;

(S730), forming a plurality of three-dimensional nano-structures **133** on a surface of the second semiconductor layer **140** away from the active layer **130**;

(S740), forming a protective layer **150** on the plurality of primary three-dimensional nano-structures **143**;

(S750), applying a cermet layer **160** on the protective layer **150**;

(S760), removing the substrate **110** to expose a surface of the first semiconductor layer **120**; and

(S770), applying a first electrode **124** to cover the exposed surface of the first semiconductor layer **120**, and a second electrode **144** electrically connected to the second semiconductor layer **140**.

The method of making LED **70** is similar to the method of making LED **60**, except the method further comprises a step of forming a plurality of primary three-dimensional nano-structures **143** on the second semiconductor layer **140**.

In step (S730), the plurality of primary three-dimensional nano-structures **143** can be formed by:

(S731), locating a mask layer on the surface of the second semiconductor layer **140**;

(S732), patterning the mask layer by a nanoimprinting and etching method;

(S733), patterning the surface of the second semiconductor layer **140** by an etching method to form a plurality of three-dimensional nano-structure performs; and

(S734), forming the plurality of the primary three-dimensional nano-structures **143** by removing the mask layer.

In step (S731), the mask layer can be a single layered structure or a multi-layered structure. In one embodiment, the

mask layer is the multi-layered structure including a first mask layer and a second mask layer disposed on a surface of the first mask layer. The first mask layer and the second mask layer are stacked on the surface of the second semiconductor layer **140** in sequence. A material of the first mask layer is ZEP520A® which is developed by Zeon Corp of Japan, a material of the second mask layer is HSQ (hydrogen silsesquioxane).

In step (S732), the mask layer can be patterned by the following steps:

(S7321), providing a patterned template, which includes a plurality of protruding structures spaced from and substantially parallel with each other, and a slot is defined between the two adjacent protruding structure;

(S7322), attaching the template on the second mask layer, and pressing the template at room temperature and removing the template to form a plurality of slots on the second mask layer;

(S7323), removing the residual second mask layer in the bottom of the slot to expose the first mask layer, and

(S7324), patterning the mask layer by removing one part of the first mask layer corresponding with the slots to expose the second semiconductor layer **140**.

In step (S733), the second semiconductor layer **140** can be placed in an inductively coupled plasma device and etched by an etching gas. In one embodiment, the etching gas is a mixed gas. The mixed gas can include Cl_2 , BCl_3 , O_2 and Ar. A power of the inductively coupled plasma device ranges from about 10 watts to about 100 watts, a flow speed of the etching gas ranges from about 8 sccm to about 150 sccm, a pressure of the etching gas can range from about 0.5 Pa to about 15 Pa, and an etching time can range from about 5 seconds to about 5 minutes. In one embodiment, the flow speed of the Cl_2 is about 26 sccm, the flow speed of the BCl_3 is about 16 sccm, the flow speed of the O_2 is about 20 sccm, and the flow speed of the Ar is about 10 sccm.

More specifically, the second semiconductor layer **140** can be etched by the following steps:

(S7331), forming a plurality of grooves with the same depth by etching the surface of second semiconductor layer **140** with the etching gas;

(S7332), continuing the etching process so that every two adjacent protruding structures begin to slant face to face to form a protruding pair; and

(S7333), further continuing the etching process so that the two adjacent protruding structures gradually slant until the tops of the two adjacent protruding structures contact each other.

In step (S7331), the etching gas etches the exposed surface of the second semiconductor layer **140** to form the plurality of grooves. The grooves have the same depth because of the same etching speed. During the etching process, the etching gas will react with the exposed second semiconductor layer **140** to form a protective layer. The protective layer will reduce the etching speed of the second semiconductor layer **140**, and the width of the grooves will slowly decrease from the outer surface of the second semiconductor layer **140** to the bottom of the grooves. Thus, the inner wall of the grooves will not be absolutely perpendicular to the surface of the second semiconductor layer **140**. The etching gas not only etches the second semiconductor layer **140**, but also etches the top of the protruding structures. The width of the top of the protruding structures will decrease. The resolution of the mask layer will not be affected because the speed of etching the top of the protruding structures is much smaller than that of the second semiconductor layer **140**. Furthermore, every two adjacent protruding structures will slant face to face.

13

In step (S7332), the tops of the two adjacent protruding structures will gradually approach to each other. The speed of etching the second semiconductor layer 140 corresponding to these two closed adjacent protruding structures will decrease, and the width of the grooves will gradually decrease from the outer surface of the second semiconductor layer 140 to the bottom of the grooves of the second semiconductor layer 140. Because the two adjacent protruding structures slant face to face to form the protruding pair, the speed of etching the second semiconductor layer 140 corresponding to the protruding pair will further decrease. Eventually, the tops of the two adjacent protruding structures contact each other, and the etching gas can no longer etch the second semiconductor layer 140 corresponding to the two adjacent protruding structures, thus the first grooves 1136 is formed on the surface of the second semiconductor layer 140. But between every two adjacent protruding pairs, the etching speed will change less than the etching speed between the slant two adjacent protruding structures. Thus the second grooves 1138 are formed, and the depth of the second grooves 1138 will be greater than that of the first grooves 1136. The plurality of three-dimensional nano-structure preforms is obtained.

In step (S734), the primary three-dimensional nano-structures 143 can be obtained by dissolving the mask layer. The mask layer can be dissolved in a stripping agent such as tetrahydrofuran (THF), acetone, butanone, cyclohexane, hexane, methanol, or ethanol. In one embodiment, the stripping agent is butanone, and the mask layer is dissolved in butanone and separated from the second semiconductor layer 140.

The plurality of primary three-dimensional nano-structures 143 also can be formed on the surface of the active layer 130 away from the first semiconductor layer 120 or the surface of the first semiconductor layer 120 adjacent to the active layer 130 by the above method. The protective layer 150 and the cermet layer 160 are directly grown on the surface of the plurality of three-dimensional nanostructures 133, thus the protective layer 150 and the cermet layer 160 also form a patterned surface.

In the method for making the LED 70, the nanoimprinting and etching method is used to form the plurality of primary three-dimensional nano-structures 143. The nanoimprinting process can be conducted in a room temperature and the template can be directly used without being pre-treated. Therefore, the method has a simple process and low cost. In addition, a large area array of the plurality of M-shaped primary three-dimensional nano-structures 143 can be fabricated for the two adjacent protruding structures of the mask layer can be contact with each other by the gas etching to form the plurality of protruding pairs. Therefore, a yield of the LED 70 can be increased.

Referring to FIG. 12, one embodiment of an LED 80 includes a first semiconductor layer 120, an active layer 130, a second semiconductor layer 140, a protective layer 150, and a cermet layer 160 stacked in that order. The first semiconductor layer 120 includes a first surface 121 and a second surface 122 opposite to the first surface. The active layer 130 is located on the second surface 122. A reflector layer 170 covers and directly contacts a surface of the cermet layer 160 away from the active layer 130. A first electrode 124 covers and directly contacts the first surface 121 of the first semiconductor layer 120 away from the active layer 130. A second electrode 144 is electrically connected to the second semiconductor layer 140.

The structure of LED 80 is similar to the structure of the LED 70, except that the structure of the LED 80 further includes the reflector layer 170 located on the cermet layer 160. The material of the reflector can be selected from Ti, Ag,

14

Al, Ni, Au, or any combination thereof. The reflector layer 170 includes a smooth surface having a high reflectivity. The photons reach the reflector layer 170 and will be reflected, thus these photons can be extracted out of the LED 70, and the light extraction efficiency of the LED 70 through the first semiconductor layer 120 can be improved. The reflector layer 170 can also be a plurality of microstructures on the surface of the cermet layer 160. The microstructure can be a groove and a bulge. Furthermore, the first electrode 124 can be transparent.

Referring to FIG. 13, one embodiment of a solar cell 22 using semiconductor structure 10 includes a first collecting electrode 32, the substrate 110, the buffer layer 116, the first silicon layer 126, a photovoltaic layer 136, a second silicon layer 146, a protective layer 150, a cermet layer 160, and a second collecting electrode 34. The substrate 110, the buffer layer 116, the first silicon layer 126, the photovoltaic layer 136, the second silicon layer 146, the protective layer 150, and the cermet layer 160 are stacked on a surface of the first collecting electrode 32 in the listed sequence.

The semiconductor type of the first silicon layer 126 and the second silicon layer 146 are different. The first silicon layer 126 can be N-typed or P-typed. In one embodiment, the first silicon layer 126 is P-typed, and the second silicon layer 146 is N-typed.

The first collecting electrode 32 and the second collecting electrode 34 can be made with the same material or different materials. The first collecting electrode 32 or the second collecting electrode 34 can be a metal plate with a continuous surface. The material of the first collecting electrode 32 or the second collecting electrode 34 can be selected from the group consisting of Al, Cu, Ag, and combinations thereof. A thickness of the first collecting electrode 32 or the second collecting electrode 34 can be in a range from about 50 nanometers to about 300 nanometers. In one embodiment, both the first collecting electrode 32 and the second electrode 34 are bar-shaped Al foils with the thickness of about 200 nanometers.

The solar cell 22 includes a light-input surface 310 and a light-output surface 320. One side of the substrate 110, the buffer layer 116, the first silicon layer 126, the photovoltaic layer 136, the second silicon layer 146, the protective layer 150, and the cermet layer 160 constitute the light-input surface 310. An opposite side of the side of the substrate 110, the buffer layer 116, the first silicon layer 126, the photovoltaic layer 136, the second silicon layer 146, the protective layer 150, and the cermet layer 160 constitute the light-output surface 320 of the solar cell 22.

Sunlight irradiates the light-input surface 310 and reaches the cermet layer 160. The metallic plasma is then generated from the cermet layer 160. The metallic plasma is absorbed by a P-N junction formed by the first silicon layer 126 and the second silicon layer 136 to form larger amounts of electrons and holes. The electrons move to the second collecting electrode 34 and the holes move to the first collecting electrode 32 to form a current.

Referring to FIG. 14, one embodiment of a waveguide tube 44 is provided. The waveguide tube 44 is substantially the same as the semiconductor structure 10. The cermet layer 160 of the waveguide tube 44 includes two substantially parallel and opposite sides: a first side 161 and a second side 162. Electromagnetic waves can enter from the first side 161 and pass through from the second side 162. The metallic plasma is generated when the electromagnetic waves reaches the cermet layer 160. The metallic plasma carrying information of the electromagnetic waves spreads in the cermet layer 160 and then converted back to the electromagnetic waves when

15

reaching the second side **162**. Therefore, the waveguide tube **44** can conduct the electromagnetic waves.

Referring to FIG. **15**, a curve between the Angular frequency and the Purcell Factor of the LED **50** of FIG. **7** is shown. A mass percent of the silicon dioxide in the cermet layer **160** is defined as factor "A". The factor A can be 0%, 10%, 20%, 30%, 40%. A dotted line shows a photoluminescence intensity of LED **50**. The smaller the distance between the curve line and the dotted line is, the more metallic plasma can be activated in the cermet layer **160**. Thus, while the factor A is about 20% or about 30%, the cermet layer **160** generates more metallic plasma, and the light extraction efficiency of the LED **50** can be improved.

It is to be understood that the above-described embodiments are intended to illustrate rather than limit the present disclosure. Variations may be made to the embodiments without departing from the spirit of the present disclosure as claimed. Elements associated with any of the above embodiments are envisioned to be associated with any other embodiments. The above-described embodiments illustrate the scope of the present disclosure but do not restrict the scope of the present disclosure.

Depending on the embodiment, certain of the steps of methods described may be removed, others may be added, and the sequence of steps may be altered. It is also to be understood that the description and the claims drawn to a method may include some indication in reference to certain steps. However, the indication used is only to be viewed for identification purposes and not as a suggestion as to an order for the steps.

What is claimed is:

1. A light emitting diode comprising:
 - a first semiconductor layer;
 - an active layer on the first semiconductor layer;
 - a second semiconductor layer on the active layer;
 - a cermet layer on the second semiconductor layer, wherein
 - a refractive index of the cermet layer is a complex number comprising a real part and an imaginary part, and the imaginary part is greater than or smaller than 0, and a dielectric constant of the cermet layer is a complex number comprising a real part and an imaginary part, and the real part of the dielectric constant is a negative number;
 - a first electrode covering entire surface of the first semiconductor layer away from the active layer; and
 - a second electrode electrically connected to the second semiconductor layer.
2. The light emitting diode of claim 1, wherein a material of the cermet layer comprises a metal material and a dielectric material.

16

3. The light emitting diode of claim 2, wherein a mass percent of the dielectric material is smaller than or equal to 40%.

4. The light emitting diode of claim 2, wherein the metal material is selected from the group consisting of gold, silver, aluminum, copper, and alloy thereof.

5. The light emitting diode of claim 2, wherein the dielectric material is selected from the group consisting of silicon, silicon dioxide, and ceramic.

6. The light emitting diode of claim 2, wherein the cermet layer comprises silver and silicon dioxide.

7. The light emitting diode of claim 6, wherein a mass percent of the silicon dioxide is about 20%.

8. The light emitting diode of claim 1, further comprising a plurality of primary three-dimensional nano-structures on a surface of the second semiconductor layer away from the active layer.

9. The light emitting diode of claim 8, wherein the plurality of primary three-dimensional nano-structures is aligned side by side, and each of the plurality of primary three-dimensional nano-structures has a first peak and a second peak aligned side by side, a first groove is defined between the first peak and the second peak, a second groove is defined between every two adjacent primary three-dimensional nano-structures, a depth of the first groove is smaller than a depth of the second groove, and a cross section of each of the plurality of the primary three-dimensional nano-structures is M-shaped.

10. The light emitting diode of claim 9, wherein the cermet layer is stacked on the plurality of primary three-dimensional nano-structures.

11. The light emitting diode of claim 10, wherein a surface of the cermet layer has a plurality of secondary three-dimensional nano-structures, and a distribution and alignment of the secondary three-dimensional nano-structures is the same as a distribution and alignment of the primary three-dimensional nano-structures.

12. The light emitting diode of claim 9, wherein the plurality of primary three-dimensional nano-structures, the first peak, and the second peak extend substantially parallel with the surface of the second semiconductor layer.

13. The light emitting diode of claim 1, wherein the cermet layer is located on a surface of the second semiconductor layer and in contact with the second semiconductor layer.

14. The light emitting diode of claim 8, further comprising a plurality of the primary three-dimensional nano-structures on a surface of the first semiconductor layer, and the active layer.
